PC C64 editions are considered to be free of any charge. Prediction of high-risk, advanced

prostate cancer: a comparison between preoperative and postoperative extended prostate-specific antigen. We present a comparison between preoperative and postoperative extended prostate-specific antigen (PSA) and transrectal ultrasound-guided biopsy in the prediction of high-risk, advanced prostate cancer. Preoperatively, 100 men who were diagnosed by Trans-rectal Ultrasound (TRUS) biopsy as having prostate cancer, had a preoperative PSA level less than 10 ng/mL, and then had radical prostatectomy (RP) were analysed. The patients were divided into four groups according to their postoperative PSA levels: (1) negative, (2) low, (3) intermediate and (4) high. The differences in the prediction rate of high-risk cancer according to preoperative PSA, postoperative PSA, PSA density (PSAD) and the postoperative PSA level with an active treatment were investigated. The postoperative high-risk cancer prediction rate according to the postoperative PSA level was 42.5% in patients with a normal postoperative PSA (4.0 ng/mL), 55.8% in those with a low postoperative PSA (0.05-2.99 ng/mL), 70.9% in those with an intermediate postoperative PSA (3.0-10.99 ng/mL) and 87.7% in patients with a high postoperative PSA (greater than 10.0 ng/mL) (P
